#### 1 Introduction

Words
Objectivity
Relations
Language
Datatypes

The World Programming Language is a stream of data characterized by datatypes and the evaluation of those. First the datatypes are recognized in the lexical analyser, then they're associated with values. Some values are given directly like numbers, strings, dates, URLs, e-mail adresses, etc., others need to be looked up using words. Words can represent variables holding any value. Words also represent operators and functions. Operators and functions are the basis of computations.

Datatypes come in three categories:

#### • Atomic datatypes

Can't be split into smaller parts.

Examples: integer!, real!, logic!, char!, word!, ...

#### • Component datatypes

Have a well defined number of components.

Examples: complex!, pair!, date!, time!, ...

#### • Series datatypes

Have zero, one of more components.

Examples: string!, file!, block!, binary!, image!, ...

Values cause two types of evaluation:

#### • Non-computing evaluation

Values, that are just data.

Examples: integer!, string!, word!, block!, ...

#### • Computing evaluation

These will cause some further computing.

Examples: Words representing an operator!, a function!, ...

Operators take precedence over function calls. This can be overruled using parentheses. Operators are infix and always take two arguments. A sequence of operators (with values in between) are computed from left to right. Function calls are always prefix followed by zero, one or more arguments.

World has no keywords. Operators and functions are represented by words, and they can be redefined at will.

# 2 Datatypes

### 2.1 Hierarchy

Hierarchy of datatypes and typesets:

```
any-type!
     unset!
     none!
     logic!
     scalar!
          number!
               integer!
               real!
               complex!
               percent!
          char!
          range!
          tuple!
          time!
     date!
     series!
          any-string!
               string!
               binary!
               file!
               url!
               tag!
               issue!
          any-block!
               block!
               any-paren!
                    paren!
               any-path!
                     path!
                     \operatorname{set}-\operatorname{path}!
                     get-path!
lit-path!
     {\it datatype!}
     typeset!
     bitset!
     any-word!
          word!
          \operatorname{set}\operatorname{-word}!
          get-word!
          lit -word!
          refinement!
     any-function!
          operator!
          function!
          routine!
     any-object!
          context!
          error!
```

port! library! KWATZ!

- 2.2 unset!
- 2.3 none!
- 2.4 logic!

### 2.5 integer!

Integers are 64-bit. The apostrophe character, ', can be used anywhere in integers beyond the first position to separate digits. A plus, +, or minus, -, can be prefixed to indicate sign. Leading zeros are ignored.

Spec	Integer	Hex
Lowest value	-9'223'372'036'854'775'808	#{8000 0000 0000 0000}
Highest value	9'223'372'036'854'775'807	#{7fff ffff ffff ffff}

#### Examples:

 $0 \\ 1 \\ -0716 \\ +42 \\ 86,400$ 

#### 2.6 real!

Reals are 64-bit double precision floating point numbers. They comply with the IEEE 754 standard. The apostrophe character, ', can be used anywhere in reals beyond the first position to separate digits. A plus, +, or minus, -, can be prefixed to indicate sign. Period, ., or comma, ,, can be used to indicate decimal point. Scientific notation (using e or E) can be used. Leading zeros are ignored. Trailing zeros after the decimal point are ignored.

When reals are shown, it is with the number of digits known (not including trailing zeros). This mean, the uncertainty on the last digit shown is always less than one. The one exception is the smallest number, 5e-324, where the uncertainty also is 5e-324.

Examples:

Spec	Real	Hex
Lowest value	-1.797'693'134'862'315'7e308	#{ffef ffff ffff ffff}
Smallest negative	-5e-324	<b>#</b> {8000 0000 0000 0001}
Smallest positive	5e-324	<b>#</b> {0000 0000 0000 0001}
Highest value	1.797'693'134'862'315'7e308	#{7fef ffff ffff ffff}

```
\begin{array}{lll} & w > 0. \\ & = 0.0 \\ & w > .1 \\ & = 0.1 \\ & w > pi \\ & = 3.141592653589793 \\ & w > e: 2.718'281'828'459'045 \\ & = 2.718281828459045 \\ & w > sqrt 2 \\ & = 1.414213562373095 \\ & w > 2 ** 53 \\ & = 9.007199254740992e+15 \\ & w > -1.12321e-320 \\ & = -1.123e-320 \end{array}
```

### 2.7 complex!

### 2.8 percent!

### 2.9 char!

If a char is constructed as an escape sequence starting with a caret, ^, the result is mapped depending on what follows the caret:

ASCII Code	Character	Maps to	Definition
33	#"^!"	30	control code
45	#"^-"	9	tab
47	#"^/"	10	newline
64 - 93	#"^@" - #"^]"	0 - 29	control codes
95	#"^_"	31	control code
97 - 122	#"^a" - #"^z"	1 - 26	control codes
126	#"^~"	127	del

For the rest, the caret has no effect. Notice how to specify these special characters:

Characters can also be specified using hex form:

Character	Definition
#"^^"	caret character
#"^""	quotation mark

- 2.10 range!
- 2.11 tuple!
- 2.12 time!
- 2.13 date!
- 2.14 string!

Character	Definition
^^	caret character
^ II	quotation mark
^{	opening brace (curly begin)
^}	closing brace (curly end)

# 2.15 binary!

Example:

w> #{0102} == #{0102}

- 2.16 file!
- 2.17 url!
- 2.18 tag!
- 2.19 issue!
- 2.20 block!
- 2.21 paren!
- 2.22 path!
- 2.23 set-path!
- 2.24 get-path!
- 2.25 lit-path!
- 2.26 datatype!
- 2.27 typeset!
- 2.28 bitset!
- 2.29 word!
- 2.30 set-word!
- 2.31 get-word!
- 2.32 lit-word!
- 2.33 refinement!
- 2.34 operator!
- 2.35 function!

#### 2.36 routine!

#### **Interface Specification**

```
routine—name: make routine! [
    "routine description"
    [special attributes]
    library "routine—name" [
         argument1 [arg1—world—type] arg1—type
        "argument1 description"
         argument2 [arg2—world—type] arg2—type
        "argument2 description"
        ...
]
return—type return—world—type
]
```

Special attributes can be:

typecheck Will check and eventually convert datatypes

The following fields are optional:

- Routine description (string!)
- Special attributes (block!)
- Argument block, in case there are no arguments (block!)
- Argument names (argument1 and argument2 in the above) (word!)
- Argument description (string!)
- Return World type, in case special attribute, typecheck, isn't set

Typical combinations of World types and argument types:

World type	Argument type	Description
integer!	uint8	Unsigned 8-bit integer
integer!	sint8	Signed 8-bit integer
integer!	uint16	Unsigned 16-bit integer
integer!	sint16	Signed 16-bit integer
integer!	uint32	Unsigned 32-bit integer
integer!	sint32	Signed 32-bit integer
integer!	uint64	Unsigned 64-bit integer
integer!	sint64	Signed 64-bit integer
real!	float	32-bit floating point
real!	double	64-bit floating point
char!	uchar	Unsigned char
char!	schar	Signed char
integer!	ushort	Unsigned short
integer!	sshort	Signed short
integer!	uint	Unsigned integer
integer!	sint	Signed integer
integer!	ulong	Unsigned long
integer!	slong	Signed long
string!	pointer	A string

- 2.37 context!
- 2.38 error!
- 2.39 port!

#### 2.40 library!

Libraries are loaded with

```
lib: load/library %lib-file
```

Libraries don't need to be freed. When there are no more references to the library, it's being freed.

#### Mac OS X examples

```
w> libc: load/library %/usr/lib/libc.dylib
w> puts: make routine! [libc "puts" [[string!] pointer] sint
    integer!]
w> puts "Hello, World!"
Hello, World!
== 10
w> tanh: make routine! [libc "tanh" [[real!] double] double
    real!]
w> tanh 1.5
== 0.905148253644866
```

#### Windows examples

```
w> msvcrt: load/library %msvcrt.dll
w> puts: make routine! [msvcrt "puts" [[string!] pointer] sint
    integer!]
w> puts "Hello, World!"
Hello, World!
== 0
w> tanh: make routine! [msvcrt "tanh" [[real!] double] double
    real!]
w> tanh 1.5
== 0.905148253644866
```

#### 2.41 KWATZ!

# 3 Expressions

### 3.1 Arithmetic operators

Addition (+)

Subtraction (-)

Multiplication (\*)

Division (/)

Modulo (//)

The modulo operator, //, is defined as:

$$b \mathrel{//} m = b - \left(m \times floor\left(\frac{b}{m}\right)\right)$$

, where the floor(x) function gives the largest integer not greater than x.  $floor\left(b/m\right)$  is also known as  $floor\ division$ .

The result of the modulo operation is called the *remainder*.

### 3.2 Unary minus

### 3.3 Relational operators

Equal (=)

Strict equal (==)

Same (=?)

Not equal (<>)

Greater (>)

Greater or equal (>=)

Lesser (<)

Lesser or equal (<=)

#### 3.4 Logical operators

and

or

xor

#### 3.5 Math operators

Power (\*\*)

### 4 Values

#### 4.1 false

false: make logic! 0

#### 4.2 none

none: make none! 0

#### 4.3 true

true: make logic! 1

### 5 Natives

Natives are built-in functions, where the source isn't available as World source. Words representing natives may be given other values (be redefined). Natives are referred to as functions, as they work exactly like functions.

#### 5.1 Arithmetic

add

subtract

multiply

divide

 $\mathbf{mod}$ 

### 5.2 Unary minus

Unary minus is a dash, -, following immediately after one of these:

- unset!. This also include beginning of a script and beginning of input from the prompt.
- $\bullet$  set-word!
- native!
- operator!
- A function!, that takes at least one argument.

- $\bullet\,$  The beginning of a parenthesis.
- The beginning of a block being reduced or evaluated.

Unary minus behaves like  $\mathbf{negate}$ .

Examples of the above seven situations:

```
- pi
a: - 42
print - e
a * - b
my-func - a b c
(- x + y)
do [- x + y]
```

The following all give the same result:

```
e ** - x ** 2

e ** negate x ** 2

e ** -(x ** 2)

e ** (-(x ** 2))
```
