#### 1 Introduction

Words
Objectivity
Relations
Language
Datatypes

The World Programming Language is a stream of data characterized by datatypes and the evaluation of those. First the datatypes are recognized in the lexical analyser, then they're associated with values. Some values are given directly like numbers, strings, dates, URLs, e-mail adresses, etc., others need to be looked up using words. Words can represent variables holding any value. Words also represent operators and functions. Operators and functions are the basis of computations.

Datatypes come in three categories:

#### • Atomic datatypes

Can't be split into smaller parts.

Examples: integer!, real!, logic!, char!, word!, ...

#### • Component datatypes

Have a well defined number of components.

Examples: complex!, pair!, date!, time!, ...

#### • Series datatypes

Have zero, one of more components.

Examples: string!, file!, block!, binary!, image!, ...

Values cause two types of evaluation:

#### • Non-computing evaluation

Values, that are just data.

Examples: integer!, string!, word!, block!, ...

#### • Computing evaluation

These will cause some further computing.

Examples: Words representing an operator!, a function!, ...

Operators take precedence over function calls. This can be overruled using parentheses. Operators are infix and always take two arguments. A sequence of operators (with values in between) are computed from left to right. Function calls are always prefix followed by zero, one or more arguments.

World has no keywords. Operators and functions are represented by words, and they can be redefined at will.

## 2 Datatypes

#### 2.1 Hierarchy

Hierarchy of datatypes and typesets:

```
any-type!
     unset!
     none!
     logic!
     scalar!
         number!
               integer!
               real!
               complex!
               percent!
          char!
         range!
          tuple!
         time!
     date!
     series!
         any-string!
               string!
               binary!
               file!
               url!
               tag!
               issue!
         any-block!
               block!
              any-paren!
                   paren!
              any-path!
                    path!
                    \operatorname{set}-\operatorname{path}!
                    get-path!
lit-path!
     datatype!
     typeset!
     bitset!
     any-word!
         word!
         \operatorname{set-word}!
         get-word!
         lit -word!
         refinement!
     any-function!
         operator!
          function!
         routine!
     any-object!
         context!
          error!
```

port! handle! struct! library! KWATZ!

- 2.2 unset!
- 2.3 none!
- 2.4 logic!

#### 2.5 integer!

Integers are 64-bit. The apostrophe character, ', can be used anywhere in integers beyond the first position to separate digits. A plus, +, or minus, -, can be prefixed to indicate sign. Leading zeros are ignored.

| Spec          | Integer                    | Hex                    |
|---------------|----------------------------|------------------------|
| Lowest value  | -9'223'372'036'854'775'808 | #{8000 0000 0000 0000} |
| Highest value | 9'223'372'036'854'775'807  | #{7fff ffff ffff ffff} |

#### Examples:

 $0 \\ 1 \\ -0716 \\ +42 \\ 86,400$ 

#### 2.6 real!

Reals are 64-bit double precision floating point numbers. They comply with the IEEE 754 standard. The apostrophe character, ', can be used anywhere in reals beyond the first position to separate digits. A plus, +, or minus, –, can be prefixed to indicate sign. Period, ., or comma, ,, can be used to indicate decimal point. Scientific notation (using e or E) can be used. Leading zeros are ignored. Trailing zeros after the decimal point are ignored.

| Spec              | Real                         | Hex                            |
|-------------------|------------------------------|--------------------------------|
| Lowest value      | -1.797'693'134'862'315'7e308 | #{ffef ffff ffff ffff}         |
| Smallest negative | -5e-324                      | #{8000 0000 0000 0001}         |
| Smallest positive | 5e-324                       | <b>#</b> {0000 0000 0000 0001} |
| Highest value     | 1.797'693'134'862'315'7e308  | #{7fef ffff ffff ffff}         |
| Infinite          | inf                          | #{7FF0 0000 0000 0000}         |
| - Infinite        | -inf                         | #{FFF0 0000 0000 0000}         |
| Not a Number      | nan                          | #{FFF8 0000 0000 0000}         |

When reals are shown, it is with the number of digits known (not including trailing zeros). This mean, the uncertainty on the last digit shown is always less than one. The one exception is the smallest number, 5e-324, where the uncertainty also is 5e-324.

Examples:

```
w > 0.
= 0.0
w > .1
= 0.1
w> pi
= 3.141592653589793
w> e: 2.718'281'828'459'045
= 2.718281828459045
w > sqrt 2
= 1.414213562373095
w\!\!>~2~**~53
= 9.007199254740992e+15
w > -1.12321e -320
= -1.123e - 320
w > 1 / 0
== inf
w > -1 / 0
==-\operatorname{i} n\, f
w > 0 / 0
== nan
```

#### 2.7 complex!

#### 2.8 percent!

#### 2.9 char!

If a char is constructed as an escape sequence starting with a caret, ^, the result is mapped depending on what follows the caret:

| ASCII Code | Character     | Maps to | Definition    |
|------------|---------------|---------|---------------|
| 33         | #"^!"         | 30      | control code  |
| 45         | #"^-"         | 9       | tab           |
| 47         | #"^/"         | 10      | newline       |
| 64 - 93    | #"^@" - #"^]" | 0 - 29  | control codes |
| 95         | #"^_"         | 31      | control code  |
| 97 - 122   | #"^a" - #"^z" | 1 - 26  | control codes |
| 126        | #"^~"         | 127     | del           |

For the rest, the caret has no effect. Notice how to specify these special characters:

| Character | Definition      |
|-----------|-----------------|
| #"^^"     | caret character |
| #"^""     | quotation mark  |

Characters can also be specified using hex form:

- 2.10 range!
- 2.11 tuple!
- 2.12 time!
- 2.13 date!
- 2.14 string!

| Character | Definition                  |  |
|-----------|-----------------------------|--|
| ^^        | caret character             |  |
| ^ II      | quotation mark              |  |
| ^{        | opening brace (curly begin) |  |
| ^}        | closing brace (curly end)   |  |

## 2.15 binary!

#### Example:

- 2.16 file!
- 2.17 url!
- 2.18 tag!
- 2.19 issue!
- 2.20 block!
- 2.21 paren!
- 2.22 path!
- 2.23 set-path!
- 2.24 get-path!
- 2.25 lit-path!
- 2.26 datatype!
- 2.27 typeset!
- 2.28 bitset!
- 2.29 word!
- 2.30 set-word!
- 2.31 get-word!
- 2.32 lit-word!
- 2.33 refinement!
- 2.34 operator!
- 2.35 function!

#### 2.36 routine!

#### **Interface Specification**

```
routine—name: make routine! [
    "routine description"
    [special attributes]
    library "routine—name" [
         argument1 [arg1—world—type] arg1—type
        "argument1 description"
         argument2 [arg2—world—type] arg2—type
        "argument2 description"
        ...
]
return—type return—world—type
]
```

Special attributes can be:

typecheck Will check and eventually convert datatypes

The following fields are optional:

- Routine description (string!)
- Special attributes (block!)
- $\bullet$  Argument block, in case there are no arguments (block!)
- Argument names (argument1 and argument2 in the above) (word!)
- Argument World types (datatype! or word!), if typecheck isn't specified
- Argument description (string!)
- Return World type (datatype! or word!)

Typical combinations of World types and argument types:

| World type | Argument type | Description             |
|------------|---------------|-------------------------|
| integer!   | uint8         | Unsigned 8-bit integer  |
| integer!   | sint8         | Signed 8-bit integer    |
| integer!   | uint16        | Unsigned 16-bit integer |
| integer!   | sint16        | Signed 16-bit integer   |
| integer!   | uint32        | Unsigned 32-bit integer |
| integer!   | sint32        | Signed 32-bit integer   |
| integer!   | uint64        | Unsigned 64-bit integer |
| integer!   | sint64        | Signed 64-bit integer   |
| real!      | float         | 32-bit floating point   |
| real!      | double        | 64-bit floating point   |
| char!      | uchar         | Unsigned char           |
| char!      | schar         | Signed char             |
| integer!   | ushort        | Unsigned short          |
| integer!   | sshort        | Signed short            |
| integer!   | uint          | Unsigned integer        |
| integer!   | sint          | Signed integer          |
| integer!   | ulong         | Unsigned long           |
| integer!   | slong         | Signed long             |
| string!    | pointer       | A string                |
| binary!    | pointer       | A binary                |
| struct!    | pointer       | A structure as in C     |
| handle!    | pointer       | A handle                |

When argument type is pointer, World type can be string!, binary! or handle!. Some routines take a pointer to a handle as argument, and the routine will then update the handle. To achieve this, argument type should be set to

#### pointer-adr

Next when the handle's value is used in new routines, argument type should be pointer.

Remember to set typecheck, when using handles.

- 2.37 context!
- 2.38 error!
- 2.39 port!
- 2.40 handle!

#### 2.41 struct!

Some routines in external libraries take C structures as arguments. In World such structures can be defined with the struct! datatype.

#### **Specification**

```
struct—name: make struct! [[
    "struct description"
    C—datatype argument1 "argument1 description"
    C—datatype argument2 "argument2 description"
    ...
] [
    Block of initial values
]]
```

Instead of the block of initial values, **none** can be specified, which will set the memory area to zeros.

The C datatype and argument can be given in reverse order. Example:

```
float1: make struct! [[
    float f
] none]

float2: make struct! [[
    f float
] none]
```

The following fields are optional:

- Struct description (string!)
- Argument description (string!)

The C datatype can be the same as the argument type for routines: uint8, sint8, uint16, sint16, uint32, sint32, uint64, sint64, float, double, uchar, schar, ushort, short, uint, sint, ulong, slong and pointer.

#### 2.42 library!

Libraries are loaded with

```
lib: load/library %lib-file
```

Libraries don't need to be freed. When there are no more references to the library, it's being freed.

#### Mac OS X examples

```
w> libc: load/library %/usr/lib/libc.dylib
w> puts: make routine! [libc "puts" [[string!] pointer] sint
    integer!]
w> puts "Hello, World!"
Hello, World!
== 10
w> tanh: make routine! [libc "tanh" [[real!] double] double
    real!]
w> tanh 1.5
== 0.905148253644866
```

#### Windows examples

```
w> msvcrt: load/library %msvcrt.dll
w> puts: make routine! [msvcrt "puts" [[string!] pointer] sint
    integer!]
w> puts "Hello, World!"
Hello, World!
== 0
w> tanh: make routine! [msvcrt "tanh" [[real!] double] double
    real!]
w> tanh 1.5
== 0.905148253644866
```

#### 2.43 KWATZ!

## 3 Expressions

### 3.1 Arithmetic operators

Addition (+)

Subtraction (-)

Multiplication (\*)

Division (/)

Modulo (//)

The modulo operator, //, is defined as:

$$b \mathrel{//} m = b - \left(m \times floor\left(\frac{b}{m}\right)\right)$$

, where the floor(x) function gives the largest integer not greater than x.  $floor\left(b/m\right)$  is also known as  $floor\ division$ .

The result of the modulo operation is called the *remainder*.

#### 3.2 Unary minus

#### 3.3 Relational operators

Equal (=)

Strict equal (==)

Same (=?)

Not equal (<>)

Greater (>)

Greater or equal (>=)

Lesser (<)

Lesser or equal (<=)

#### 3.4 Logical operators

 $\mathbf{or}$ 

xor

#### 3.5 Math operators

Power (\*\*)

#### 4 Values

#### 4.1 false

false: make logic! 0

#### 4.2 none

none: make none! 0

#### 4.3 true

true: make logic! 1

#### 5 Natives

Natives are built-in functions, where the source isn't available as World source. Words representing natives may be given other values (be redefined). Natives are referred to as functions, as they work exactly like functions.

#### 5.1 Arithmetic

add

subtract

multiply

divide

 $\mathbf{mod}$ 

#### 5.2 Unary minus

Unary minus is a dash, -, following immediately after one of these:

- unset!. This also include beginning of a script and beginning of input from the prompt.
- $\bullet$  set-word!
- native!
- operator!
- A function!, that takes at least one argument.

- $\bullet\,$  The beginning of a parenthesis.
- The beginning of a block being reduced or evaluated.

Unary minus behaves like  $\mathbf{negate}$ .

Examples of the above seven situations:

```
- pi
a: - 42
print - e
a * - b
my-func - a b c
(- x + y)
do [- x + y]
```

The following all give the same result:

```
e ** - x ** 2

e ** negate x ** 2

e ** -(x ** 2)

e ** (-(x ** 2))
```
